

Snapdeal Analytics Project

Internship Project Report

This project was done as part of my Data Analytics internship. The main aim was to understand the Snapdeal product dataset and create useful analysis using Power BI and DAX. The analysis mainly focused on price, discount, ratings, reviews, promotions and inventory-related risk.

1. Tools Used

Tool	Use
Power BI	Data analysis and visualizations
Power Query	Data cleaning and preparation
DAX	Measures and calculated fields
GitHub	Project files and documentation

2. Work Completed

Task 1 – Pricing vs Satisfaction

Compared product prices with ratings and created measures related to estimated sales, category performance and product risk.

Task 2 – Promotion Analysis

Compared discounts for promotional and non-promotional products. The baseline discount was 14.67%, while the promotion discount was 69.65%. The calculated promotional lift was 54.99 percentage points.

Task 3 – Discount and Rating

Used a scatter plot to check the relationship between discount and rating. The regression slope was about 0.01, so the relationship was very weak.

Task 4 – Financial Risk

Created a KPI for financially at-risk inventory. The result from the available data was 25.40%.

Task 5 – Rating Comparison

Compared simple average, review-weighted and trust-weighted ratings. The trust-weighted rating came to 4.11.

Task 6 – Price Banding

Created low, medium and high price bands using percentile-based thresholds so that the bands respond to the selected data.

3. Main Observations

- Products with promotions had much higher discounts than non-promotional products.
- The high-discount group had the highest average review volume in the available data.
- The average rating across the review-volume groups was around 3.1.
- The discount and rating relationship was very weak, with a regression slope of about 0.01.
- The calculated financially at-risk percentage was 25.40%.
- The trust-weighted rating was 4.11.

4. Limitations of the Dataset

- The dataset did not contain enough historical data to make a proper 30-day promotion trend.
- Actual sales/transaction data was not available, so estimated sales had to be used.
- There was no actual stock history or complete inventory value data, so an estimated stock-value measure was used for the risk analysis.
- Actual product return-rate data was not available, so a proxy was used where required for the trust-weighted calculation.
- Because the dataset is mainly a snapshot, the analysis can show patterns and relationships but cannot prove that one factor directly caused another.

5. Conclusion

Through this project, I got practical experience in cleaning data, creating DAX measures, building Power BI visuals and interpreting the results. The project also helped me understand the importance of checking whether the available data is sufficient for a particular analysis. Where the required data was not available, I used reasonable calculated measures and clearly noted the limitations.
